ON MAÑÉ’S LAST CONJECTURE

DANIEL MASSART

ABSTRACT. It is not $C^4$-generic for Lagrangians to have a minimising periodic orbit.

1. INTRODUCTION

Let $M$ be a smooth, closed, connected manifold and $L$ be a Lagrangian on the tangent bundle $TM$, that is, a $C^r$, $r \geq 2$ function on $TM$ which is convex and superlinear when restricted to any fiber. The Euler-Lagrange equation then defines a complete flow $\Phi_t$ on $TM$. See [Fa00] and [Mr91] for background and reference.

Call $\mathcal{M}$ the set of compactly supported, $\Phi_t$-invariant probability measures on $TM$. The objects under scrutiny here are the measures—henceforth called minimising—that minimise the $L$-action, that is, the integral $\int_{TM}(L)d\mu$, over $\mathcal{M}$.

We say a property is true for a generic Lagrangian if, given a Lagrangian $L$, there exists a residual (countable intersection of open and dense subsets) subset $\mathcal{O}$ of $C^\infty(M)$ such that the property holds for $L + f, \forall f \in \mathcal{O}$. Mañé ([Mn96]) proved for a generic Lagrangian, there exists a unique minimising measure and in [Mn97] (see also [CDI97]) he made the following

Conjecture 1. For a generic Lagrangian, there exists a unique minimising measure and it is supported on a periodic orbit.

Given a Lagrangian $L$, denote $\mathcal{O}_L$ the set of $f \in C^\infty(M)$ such that $L + f$ has a unique minimising measure, supported on a periodic orbit. To our dismay we are going to disprove the conjecture by proving this

Theorem 2. There exists a Lagrangian $L$ on the two-torus such that the set $\mathcal{O}_L$ is not dense in the $C^4$-topology.

Our Lagrangian is just a flat metric plus a constant 1-form with the ratio of its coefficients irrational and quadratic. The idea is then to use the Diophantine approximation properties of the ratio.

See [Mn96], Problem IV for a slightly weaker conjecture and [Mt02] for a proof thereof when $M$ is a closed, orientable surface.

2. PRELIMINARIES

2.1. Globally minimising orbits. Given a $C^1$ curve $\gamma$ defined on some compact interval $I$ into $M$, the $L$-action of $\gamma$ is the integral $\int_I L(\gamma, \dot{\gamma})ds$. The curve $\gamma$ is said to be minimising if it minimises the $L$-action over all $C^1$ curves defined over the same interval, with the same endpoints. A $C^1$
curve $\gamma : \mathbb{R} \rightarrow M$ is said to be minimising if its restriction to any compact interval is. An orbit $\gamma : \mathbb{R} \rightarrow TM$ is said to be minimising if its projection to $M$ is. We denote by $G(L)$ the union in $TM$ of all minimising orbits. Note that the support of a minimising measure is always contained in $G(L)$ (see [Fa00]).

We choose an auxiliary Riemann metric on $M$ and denote by $d_{TM}$ the associated distance function on $TM$.

**Proposition 3.** The set $G(L)$ is upper semi-continuous with respect to the Lagrangian.

**Proof.** Here the topology on the $G$’s is the Hausdorff topology on compact sets, and the topology on Lagrangians is that induced by uniform convergence on compact sets of the Lagrangian and its derivatives up to second order. Then convergence of the Lagrangian ensures uniform convergence of the time $t$ map of the flow.

Let $L_n$ be a sequence of Lagrangians converging to some $L$ and denote by $\phi^n_t$ the associated flow on $TM$. First note that by a priori Compactness ([Fa00], Corollary 4.1.2) the sets $G(L_n)$ remain in a bounded region $K$ of $TM$. So all we have to show is that if a subsequence of the sets $G(L_n)$ converges, in the Hausdorff topology, to some $\Lambda$, then $\Lambda$ consists of orbits of $\Phi_t$, and those orbits are minimising.

Assume $\Lambda$ is not $\Phi_t$-invariant. Then there exists a point $(x, v)$ in $\Lambda$ and $t \in \mathbb{R}$ such that $\epsilon := d_{TM}(\Lambda, \phi_t(x, v)) > 0$. Choose $\delta$ such that

$$d_{TM}((x, v), (y, w)) \leq \delta \implies d_{TM}(\phi_s(x, v), \phi^\prime_s(y, w)) \leq \epsilon/3 \; \forall s \in [0, t].$$

Let $N$ be such that $d_{TM}(\Lambda, G_n) \leq \min(\delta, \epsilon/3)$ for all $n \geq N$. Take $(x_N, v_N)$ in $G_N$ such that $d_{TM}((x, v), (x_N, v_N)) \leq \delta$. Then by definition of $\delta$ we have $d_{TM}(\phi_t(x, v), \phi^N_t(x_N, v_N)) \leq \epsilon/3$ which implies, $G_N$ being $\Phi_t^N$-invariant, $d_{TM}(G_N, \phi_t(x, v)) \leq \epsilon/3$. Then since $d_{TM}(\Lambda, G_N) \leq \epsilon/3$ we have

$$d_{TM}(\Lambda, \phi_t(x, v)) \leq 2\epsilon/3 < \epsilon,$$

a contradiction.

Assume an orbit $\delta$ in $\Lambda$ is not minimising. Then there exists $s, t \in \mathbb{R}$, $\epsilon > 0$ and a $C^1$ curve $\gamma : [s, t] \rightarrow M$ such that $\gamma(s) = \delta(s), \gamma(t) = \delta(t)$ and

$$\int_s^t L(\gamma(\tau), \dot{\gamma}(\tau))d\tau + \epsilon \leq \int_s^t L(\delta(\tau), \dot{\delta}(\tau))d\tau.$$

Let $N_1$ be such that

$$|L_n(x, v) - L(x, v)| \leq \frac{\epsilon}{6|t - s|} \; \forall n \geq N_1, (x, v) \in K$$

and let $\alpha$ be such that

$$|L(x, v) - L(y, w)| \leq \frac{\epsilon}{6|t - s|} \; \forall (x, v), (y, w) \in K, d_{TM}((x, v), (y, w)) \leq \alpha.$$

There exists $N_2$ such that $d_{TM}(\Lambda, G_n) \leq \alpha$ for all $n \geq N_2$. Then there exists $n \geq \max(N_1, N_2)$ and an orbit $\delta_n$ in $G_n$ such that $d_{TM}(\delta_n(\tau), \delta(\tau)) \leq \alpha$ for all $\tau \in [s, t]$. By adding short segments at the ends of $\gamma([s, t])$ and
reparametrisating we construct a curve $\gamma_n\colon [s,t] \to M$ such that $\gamma_n(s) = \delta_n(s)$, $\gamma_n(t) = \delta_n(t)$. Possibly taking a larger $n$, we may assume that

$$\int_s^t L_n(\dot{\gamma}_n(\tau), \gamma_n(\tau))d\tau \leq \int_s^t L(\gamma(\tau), \dot{\gamma}(\tau))d\tau + \frac{\epsilon}{3}.$$ 

Then we have

$$\int_s^t L_n(\dot{\delta}_n(\tau), \delta_n(\tau))d\tau \geq \int_s^t L_n(\dot{\delta}(\tau), \delta(\tau))d\tau - \frac{\epsilon}{3}$$

$$\geq \int_s^t L(\delta(\tau), \dot{\delta}(\tau))d\tau - \frac{\epsilon}{3}$$

$$\geq \int_s^t L(\gamma(\tau), \dot{\gamma}(\tau))d\tau + \frac{2\epsilon}{3}$$

$$\geq \int_s^t L_n(\gamma_n(\tau), \dot{\gamma_n}(\tau))d\tau + \frac{\epsilon}{3}$$

which is impossible since all orbits in $G_n$ are minimising.

\[\square\]

2.2. The Lagrangian. Let $T^2 = (\mathbb{R}/\mathbb{Z})^2$ be the standard two-torus, let $(x, y, u, v)$ be coordinates in $T^2 \times \mathbb{R}^2$, and let $r$ be a quadratic irrational real number. Let $p, q$ be real numbers such that $p/q = r$ and $p^2 + q^2 = 1$. Let $\omega$ be the closed one-form on $T^2$ defined by $\omega(x, y)(u, v) = pu + qv$.

Now let $L$ be the Lagrangian on $T^2$ defined by

$$L(x, y, u, v) = \frac{1}{2}(u^2 + v^2) - \omega(x, y)(u, v).$$

Since the one-form $\omega$ is closed, the orbits of the Euler-Lagrange flow of $L$ are geodesics parametrized with constant speed.

Lemma 4. The critical value of the Lagrangian $L$ is $1/2$.

Proof. Let us prove that $c(L) \leq 1/2$, that is, $\int Ld\mu \geq -1/2$ for all $\mu \in \mathcal{M}$.

Since every invariant measure is a convex combination of ergodic measures, it is enough to prove it when $\mu$ is ergodic. For such a $\mu$ there exists a geodesic with velocity $(u, v)$ such that

$$\int Ld\mu = \lim_{T \to \infty} \frac{1}{T} \int_0^T \left( \frac{1}{2}(u^2 + v^2) - pu - qv \right) dt = \frac{1}{2}(u^2 + v^2) - pu - qv.$$

Now since $p^2 + q^2 = 1$ we have $pu + qv \leq \sqrt{u^2 + v^2}$ so

$$(1/2)(u^2 + v^2) - pu - qv \geq -1/2.$$

Let us prove that $c(L) \geq 1/2$. Consider the probability measure $\mu$ in $T^2 \times \mathbb{R}^2$ evenly distributed on the torus

$$\{(x, y, u, v)\colon u^2 + v^2 = 1, \ pu + qv = 1\} = \{(x, y, p, q)\colon (x, y) \in T^2\}.$$ 

We have $\int Ld\mu = -1/2$ so $c(L) = 1/2$ and $\mu$ is minimising.

\[\square\]
(p, q). This translation is ergodic since \( p/q \) is irrational so \( \Lambda \) is the normalised Lebesgue measure on \( \mathbb{T}^2 \).

**Lemma 5.** For the Lagrangian \( L \) we have \( \mathcal{G}(L) = \operatorname{supp}(\mu) \).

**Proof.** This amount to showing that if \( (\gamma, \dot{\gamma}) \) is a minimising orbit, we have \( \dot{\gamma}(t) = (p, q) \) for all \( t \). Note that an orbit is a geodesic of a flat metric so it has constant velocity. Let \( (p_1, q_1) \) be that velocity and \( 1/2(p_1^2 + q_1^2) + pp_1 + qq_1 := \epsilon > 0 \). Then we have \( \int_0^t (L + c(L))(\gamma, \dot{\gamma}) ds = t\epsilon \) so for \( t \) large enough we may connect a long segment of an orbit of velocity \( (p, q) \) with a short geodesic segment to get a curve with the same endpoints as \( \gamma([0, t]) \), same parameter interval and smaller action, showing that \( \gamma \) is not minimising. \( \square \)

Now assume there exists a sequence of \( C^2 \) functions \( f_n \) on \( \mathbb{T}^2 \), and closed curves \( \gamma_n : [0, T_n] \rightarrow \mathbb{T}^2 \) such that the uniformly distributed probability measure \( \mu_n \) on the set \( (\gamma_n, \dot{\gamma}_n)([0, T_n]) \) in \( \mathbb{T}^2 \) is \( L + f_n \)-minimising. Then in particular

\[
\int_{\mathbb{T}^2} (L + f_n) d\mu_n \leq \int_{\mathbb{T}^2} (L + f_n) d\mu = -c(L) + \int_{\mathbb{T}^2} f_n d\Lambda \text{ so}
\]

\[
(1) \quad \int_{\mathbb{T}^2} (L + c(L)) d\mu_n \leq \int_{\mathbb{T}^2} f_n d\Lambda - \int f_n d\mu_n.
\]

**2.3. Evaluation of the left-hand side in Equation 1.** Let \( \mathbb{Z}^2 \) be identified with \( H_1(\mathbb{T}^2, \mathbb{Z}) \). Let \( (p_n, q_n) \) be the homology class of \( \gamma_n \). The left-hand side of Equation 1 is minimal when \( \gamma_n \) is a geodesic of the flat metric \( \| (u, v) \| = \sqrt{u^2 + v^2} \) parametrised with energy \( c(L) \), or unit speed. Such a geodesic is given by

\[
\gamma_n : [0, \sqrt{p_n^2 + q_n^2}] \rightarrow \mathbb{T}^2, \quad t \mapsto \frac{t}{\sqrt{p_n^2 + q_n^2}}(p_n, q_n) \mod \mathbb{Z}^2.
\]

Let \( r_n \) be \( p_n/q_n \) and \( \epsilon_n \) be \( |r_n - r| \). Since \( p_n, q_n \) are integers and \( r = p/q \) is a quadratic irrational number, there exists a constant \( C_1 > 0 \) such that \( \epsilon_n \geq C_1 q_n^2 \). Then

\[
\int_{\mathbb{T}^2} (L + c(L)) d\mu_n = \frac{1}{\sqrt{p_n^2 + q_n^2}} \int_0^{\sqrt{p_n^2 + q_n^2}} \left( \frac{1}{2} \frac{pp_n + qq_n}{\sqrt{p_n^2 + q_n^2}} + \frac{1}{2} \right) dt
\]

\[
= 1 - \frac{pp_n + qq_n}{\sqrt{p_n^2 + q_n^2}} + q\sqrt{1 + r^2} - \frac{rqp_nq_n + qq_n}{\sqrt{r_n^2q_n^2 + q_n^2}}
\]

\[
= q\sqrt{1 + r^2 - \frac{1 + rr_n}{\sqrt{1 + r_n^2}}}
\]

\[
= q\sqrt{1 + r^2} \sqrt{1 + r_n^2} - (1 + rr_n)
\]

\[
= \frac{q\sqrt{1 + r^2} \sqrt{1 + \frac{r^2(1 + r + \epsilon_n)^2}{1 + (r + \epsilon_n)^2}}}{1 + r^2 \sqrt{1 + \frac{r^2(1 + r + \epsilon_n)^2}{1 + (r + \epsilon_n)^2}}}
\]

\[
= C_3 \epsilon_n^2 + o(\epsilon_n^2) \geq \frac{C_2}{q_n^4}
\]

for some positive constants \( C_2, C_3 \).
2.4. Foliation of \( \mathbb{R}^2 \) by translates of lifts of \( \gamma_n \).

**Lemma 6.** Let \( \gamma : [0, T] \rightarrow \mathbb{T}^2 \) be a \( C^1 \) simple closed curve. If there exists a direction \( v \in \mathbb{R}^2 \) such that \( \gamma(t) \notin \mathbb{R}v \) for all \( t \in [0, T] \), then \( \mathbb{R}^2 \) is foliated by translates of a given lift of \( \gamma \) in the direction \( v \).

**Proof.** Lift the situation to the universal cover \( \mathbb{R}^2 \), choose a lift of \( \gamma \) and denote it \( \gamma \). All we have to prove is that \( \gamma + s_1 v \) and \( \gamma + s_2 v \) are disjoint or equal for all \( s_1, s_2 \in \mathbb{R} \). Assume for some \( s_1, s_2 \in \mathbb{R} \), \( t_1, t_2 \in [0, T] \), we have \( \gamma(t_1) + s_1 v = \gamma(t_2) + s_2 v \). Then \( \gamma(t_1) - \gamma(t_2) = (s_2 - s_1) v \) so if \( s_1 \neq s_2 \), by Rolle’s theorem there exists \( t_3 \in [t_1, t_2] \) such that \( \gamma(t_3) \) is colinear to \( v \).

Now let us prove that for \( n \) large enough, \( \gamma_n \) satisfies the sufficient condition of the lemma. By lower semicontinuity of \( G \), we see that any limit point of \( \text{supp}(\mu_n) \), in the Hausdorff topology on compact subsets of \( T \mathbb{T}^2 \), is contained in \( \mathcal{G}(L) = \text{supp}(\mu) \). Hence the velocity vectors of \( \gamma_n \) converge uniformly to \( (p, q) \) so for large \( n \) the direction of the tangent vector \( \partial/\partial y \) is missed by \( \gamma_n \) for all \( t \in [0, T_n] \).

### 3. Proof of Theorem 2

From now on we work in \( \mathbb{R}^2 \), still denoting \( f_n \) the composition \( f_n \circ \pi \), where \( \pi \) is the projection of the universal cover of \( \mathbb{T}^2 \). So \( f_n \) is now a \( \mathbb{Z}^2 \)-periodic function and its mean value on \( \mathbb{R}^2 \) is well-defined. The mean value of \( f_n \) on \( \gamma_n \) and its translates is also well-defined since \( f_n \) is periodic on \( \gamma_n \) and its translates.

Define on the line \( \{x = 0\} \) the function \( \phi_n(y) \) as the mean value of \( f_n \) on the leaf of the foliation going through \( y \). Then \( \phi_n \) is \( C^k \) if \( f_n \) is \( C^k \) and \( \phi_n^{(k)}(y) \) is the mean value of \( \partial^{(k)} f_n / \partial y^{(k)} \) on the leaf of the foliation going through \( y \), that is

\[
\forall k \in \mathbb{N}, \quad \phi_n^{(k)}(y) = \frac{1}{T_n} \int_0^{T_n} \frac{\partial^{(k)} f_n}{\partial y^{(k)}}(x, y) \, dx.
\]

Note that the \( C^1 \)-norm of \( f_n \) is greater than or equal to that of \( \phi_n \). Indeed so if for some \( y \) we have \( \phi_n^{(1)}(y) \geq K \) for some \( K \), then there exists \( x \) such that \( \partial^{(k)} f_n / \partial y^{(k)}(x, y) \geq K \). Besides the mean value of \( \phi_n \) over \( \{x = 0\} \) equals the mean value of \( f_n \) over \( \mathbb{T}^2 \). Since \( \phi_n \) is 1-periodic and \( C^\infty \), for any \( k \), \( \phi_n^{(k)} \) vanishes at least once in \([0, 1]\).

Assume for definiteness that \( \gamma_n \) crosses \( \{x = 0\} \) at \( y = 0 \). Since \( \gamma_n \) is minimising in particular it minimises among its translates so we may assume, up to adding a constant, that \( \phi_n \geq 0 = \phi_n(0) \). Since \( \gamma_n \) crosses \( \{x = 0\} \) \( q_n \) times, there exists at least one interval in \( \{x = 0\} \) of length \( a_n \leq 1/q_n \) which is crossed exactly once by all leaves of the foliation. Assume for simplicity that this interval is \([0, a_n]\). So every value of \( \phi_n \) and its derivatives is taken at least once in \([0, a_n]\). Thus for every \( k \) in \( \mathbb{N} \), there exists \( x_k \) in \([0, a_n]\) such that \( \phi_n^{(k)}(x_k) = 0 \).

The following Proposition shows that \( \phi_n \), hence \( f_n \), does not go to zero in the \( C^8 \)-topology.

**Proposition 7.** For all \( k \) in \( \mathbb{N} \), there exists \( y_k \) in \([0, a_n]\) such that \( \phi_n^{(k)}(y_k) \geq C_2 q_n^{k-4} \).
Proof. By induction: for \( k = 0 \), Equation 1 and the Mean Value Theorem yield existence of an \( y_0 \) in \([0, 1]\) such that \( \phi_n(y_0) \geq C_2/q_n^4 \). Then, every value of \( \phi_n \) being achieved in \([0, a_n]\), we may assume \( y_0 \in [0, a_n] \).

Now assume we have proved the Proposition up to some \( k \). Then by the Fundamental Theorem of Calculus we have

\[
\phi_n^{(k)}(y_k) = |\phi_n^{(k)}(y_k) - \phi_n^{(k)}(x_k)| \leq \sup_{x \in [0,1]} |\phi_n^{(k)}(x)| |y_k - x_k|
\]

so there exists \( y_{k+1} \in [0, 1] \) such that \( \phi_n'(y_{k+1}) \geq C_2 q_n^{k+4} \) and as previously we may assume \( y_{k+1} \in [0, a_n] \). \( \square \)

Acknowledgements: the author thanks John Mather for suggesting the result, David Théret and Gonzalo Contreras for sitting through, and pointing errors in, early versions of the argument, and the Institute of Mathematics of the Academia Sinica in Taipei, Taiwan for its kind hospitality while writing this up.
