For $\lambda > -1$, on the unit ball \mathbb{B}^n and the Siegel domain D_n we have the weighted measures

$$\mathrm{d} v_{\lambda}(z) = c_{\lambda} (1 - |z|^2)^{\lambda} \, \mathrm{d} v(z), \quad \mathrm{d} v_{\lambda}(z) = \frac{c_{\lambda}}{4} (\mathrm{Im}(z_n) - |z'|^2)^{\lambda} \, \mathrm{d} v(z).$$

The corresponding weighted Bergman spaces and their kernels are

$$\begin{split} \mathcal{A}_{\lambda}^{2}(\mathbb{B}^{n}) &= L^{2}(\mathbb{B}^{n}, v_{\lambda}) \cap \operatorname{Hol}(\mathbb{B}^{n}) \quad \mathcal{A}_{\lambda}^{2}(D_{n}) = L^{2}(D_{n}, v_{\lambda}) \cap \operatorname{Hol}(D_{n}) \\ \mathcal{K}_{\mathbb{B}^{n}, \lambda}(z, w) &= \frac{1}{(1 - z \cdot \overline{w})^{\lambda + n + 1}} \quad \mathcal{K}_{D_{n}, \lambda}(z, w) = \frac{1}{\left(\frac{z_{n} - \overline{w}_{n}}{2i} - z' \cdot \overline{w}'\right)^{\lambda + n + 1}} \end{split}$$

We will use D to denote either \mathbb{B}^n or D_n .

The Toeplitz operator $T_a^{(\lambda)}$ with symbol *a* is defined by

$$T_a^{(\lambda)}: \mathcal{A}_{\lambda}^2(D) o \mathcal{A}_{\lambda}^2(D)$$

 $T_a^{(\lambda)}(f)(z) = \int_D f(w) \mathcal{K}_{D,\lambda}(z,w) \,\mathrm{d}v_{\lambda}(z).$

A very important and interesting problem: find and study commutative C^* -algebras generated by Toeplitz operators. Main strategy: find "nice" spaces of special symbols.

Some of the first nicest collections of special symbols are given by the maximal Abelian subgroups (MASG) of biholomorphisms on D. **Quasi-elliptic, E(n)**: \mathbb{T}^n -action on \mathbb{B}^n

$$t\cdot z=(t_1z_1,\ldots,t_nz_n).$$

Quasi-parabolic, P(n): $\mathbb{T}^{n-1} \times \mathbb{R}$ -action on D_n

$$(t',h)\cdot z=(t'z',z_n+h).$$

Quasi-hyperbolic, H(n): $\mathbb{T}^{n-1} \times \mathbb{R}_+$ -action on D_n

$$(t',r)\cdot z=(r^{\frac{1}{2}}t'z',rz_n).$$

Nilpotent, N(n): \mathbb{R}^n -action on D_n

$$(b,h) \cdot z = (z'+b, z_n+h+2iz' \cdot b+i|b|^2).$$

Quasi-nilpotent, N(n,k): $\mathbb{T}^k \times \mathbb{R}^{n-k}$ -action on D_n

$$(t, b, h) \cdot z = (tz_{(1)}, z_{(2)} + b, z_n + h + 2iz_{(2)} \cdot b + i|b|^2).$$

Quiroga-Barranco

Toeplitz

MASG

We will denote by $L^{\infty}(D)^G$ the space of essentially bounded *G*-invariant symbols on *D*. The group *G* is some subgroup of biholomorphisms of *D*.

Theorem (MASG Commutativity Theorem)

Let G be a MASG of the group of biholomorphisms of D. Then, the C*-algebra $\mathcal{T}^{(\lambda)}(L^{\infty}(D)^G)$ is commutative for every $\lambda > -1$. Furthermore, there is a unitary map $R : \mathcal{A}^2_{\lambda}(D) \to L^2(X)$ such that for every $a \in L^{\infty}(D)^G$

$$RT^{(\lambda)}_{a}R^{*}=\gamma_{a,\lambda}I$$

a multiplication operator where

 $\gamma_{a,\lambda}(x) = nice integral formula for a.$

|-----------------|--------------|--------------------------|--------------------------------|------------------------|-----------------------|----------------------------|
| | | | | | | |
| | | | | | | |

We have learned a few things from this theorem.

- Groups and Lie theory are important.
- The assignment $G \mapsto \mathcal{T}^{(\lambda)}(L^{\infty}(D)^G)$ yields commutative C^* -algebras for $G \in$ family of MASG.
- If *H* is a connected Abelian subgroup of biholomorphisms but not a MASG, then $\mathcal{T}^{(\lambda)}(L^{\infty}(D)^{H})$ is not commutative.

Question: Is it possible to assign commutative C^* -algebras to connected Abelian subgroups of biholomorphisms? The subgroups are not necessarily MASG.

A Hermitian metric on a complex manifold M is a Riemannian metric g such that

$$g(J(\cdot), J(\cdot)) = g(\cdot, \cdot).$$

A Kähler manifold (M, g) is a complex manifold M with a Hermitian metric g such that the 2-form $\omega = g(J(\cdot), \cdot)$ is closed. The form ω is called the symplectic form of M. The Hermitian metric g can be complexified to a sesquilinear tensor g and in this case the symplectic form is given by

$$\omega = -2\mathrm{Im}(g).$$

A symplectic manifold (M, ω) is a manifold M together with a non-degenerate closed 2-form ω . Example: Every Kähler manifold is symplectic. On a symplectic manifold M, if $f : M \to \mathbb{R}$ is a smooth function, then the Hamiltonian vector field of f is the smooth vector field X_f such that

$$\mathrm{d}f=\omega(X_f,\cdot).$$

Compare with the Riemannian case: On a Riemannian manifold (M, g), if $f : M \to \mathbb{R}$ is a smooth function, then the gradient of f is the smooth vector field ∇f such that

$$\mathsf{d} f = g(\nabla f, \cdot).$$

Conversely, a smooth vector field X on a symplectic manifold M is called Hamiltonian if there is a smooth function $f: M \to \mathbb{R}$ such that

Symplectic geometry

$$\mathsf{d}f = \omega(X, \cdot),$$

i.e. the 1-form $\omega(X, \cdot)$ is exact.

The form $\omega(X, \cdot)$ is not always closed, but for a vector field X the following are equivalent.

- $\omega(X, \cdot)$ is closed.
- $L_X \omega = 0.$
- The local flow of X preserves ω, i.e. acts by symplectomorphisms.

We will denote by $\mathcal{X}(M, \omega)$ the Lie algebra of all vector fields on M satisfying these conditions. The elements of $\mathcal{X}(M, \omega)$ are called symplectic vector fields.

Toeplitz

| | | | | | | |

For f, g smooth functions on the symplectic manifold M we define their Poisson brackets by

$$\{f,g\} = \omega(X_f,X_g).$$

Then, $(C^{\infty}(M), \{\cdot, \cdot\})$ is Lie algebra and the map

$$C^{\infty}(M) o \mathcal{X}(M,\omega)$$

 $f \mapsto X_f$

is an anti-homomorphism of Lie algebras: $[X_f, X_g] = -X_{\{f,g\}}$.

Let H be a connected Lie group acting by symplectomorphisms on (M, ω) :

Symplectic geometry

$$\omega(\mathsf{d}h(\cdot),\mathsf{d}h(\cdot)) = \omega(\cdot,\cdot),$$

for all $h \in H$.

For every $X \in \mathfrak{h}$ we consider the vector field X^{\sharp} on M given by

$$X_z^{\sharp} = rac{\mathsf{d}}{\mathsf{d}s}\Big|_{s=0}\exp(sX)z.$$

In particular, $X^{\sharp} \in \mathcal{X}(M, \omega)$. It is easy to see that the map

$$\mathfrak{h} o \mathcal{X}(M,\omega)$$

 $X \mapsto X^{\sharp}$

is an anti-homomorphism of Lie algebras.

The previous discussion leads us to consider the diagram

$$\mathfrak{h} \xrightarrow{\mu} \mathcal{X} \stackrel{f}{\underset{X \mapsto X^{\sharp}}{\overset{\mu}{\longrightarrow}}} \mathcal{X}(M, \omega)$$

where we want consider the existence of μ : $\mathfrak{h} \longrightarrow C^{\infty}(M)$ so that this diagram commutes. In other words

$$X_{\mu(X)} = X^{\sharp}$$

for all $X \in \mathfrak{h}$. Such a map is equivalent to maps

- $M \times \mathfrak{h} \to \mathbb{R}$,
- $M \to \mathfrak{h}^*$, where \mathfrak{h}^* is the vector space dual of \mathfrak{h} .

It is customary and convenient to use the last realization.

| | | | | | | |

Definition

If *H* is a Lie group acting by symplectomorphisms on (M, ω) , then a moment map for the *H*-action is a smooth map $\mu : M \to \mathfrak{h}^*$ such that

1 For every $X \in \mathfrak{h}$, the smooth function $\mu_X : M \to \mathbb{R}$ defined by

$$\mu_X(z) = \langle \mu(z), X \rangle$$

has Hamiltonian vector field given X^{\sharp} : $X^{\sharp} = X_{\mu_X}$.

2 For every $h \in H$ we have $\mu \circ h = Ad^*(h) \circ \mu$.

If H is Abelian, the second condition is just H-invariance:

$$\mu \circ \mathbf{h} = \mu$$

for all $h \in H$.

We are interested in the connected Abelian groups of biholomorphisms of D.

If G is such a MASG, then $\mathfrak{g} = \mathbb{R}^n$ and so we have a natural identification $\mathfrak{g}^* = \mathbb{R}^n$.

If *H* is a connected Abelian group of biholomorphisms, up to conjugacy, we can assume $H \subset G$, where *G* is some MASG. Hence, $\mathfrak{h} \subset \mathbb{R}^n$ and so $\mathfrak{h}^* = \mathfrak{h}$.

6 β -symbols

7 Spectral integral formulas

We can describe specific types of symbols by describing explicitly the moment maps of connected Abelian groups. Some general facts:

• Every connected Abelian group *H* of biholomorphisms of *D* is contained in a MASG *G*.

 β -symbols

There is a one-to-one correspondence between the connected subgroups of a MASG *G* and subspaces \mathfrak{h} of \mathbb{R}^n given by

$$\mathfrak{h}\mapsto \exp(\mathfrak{h})$$

where exp is the exponential map of G.

• To introduce coordinates, consider linearly independent sets $\beta \subset \mathbb{R}^n$. Hence, there is a correspondence (onto only)

$$\beta \mapsto \exp(\mathbb{R}\langle \beta \rangle)$$

where $\mathbb{R}\langle\beta\rangle$ denotes the subspace generated by β .

Corollary

If $\beta = \{v_1, \dots, v_m\}$ is an arbitrary basis of \mathfrak{h} , then the moment map functions are precisely those of the form $a(z) = f(a_1(z), \dots, a_m(z))$, where

$$a_j(z) = \langle \mu^{G}(z), v_j
angle$$

for j = 1, ..., m.

Definition

The symbols from the Corollary are called β -symbols. The essentially bounded β -symbols are denoted by $L^{\infty}(D)_{\beta}$.

Corresponding to the choice of G we have β -quasi-elliptic, β -quasi-parabolic, β -quasi-hyperbolic, β -nilpotent and β -quasi-nilpotent symbols.

Quiroga-Barranco

Every currently known family of symbols whose Toeplitz operators generate commutative C^* -algebras on every weighted Bergman space of D is a set of β -symbols for some β . For example, quasi-radial symbols corresponding to a partition $k \in \mathbb{N}^m$ of n are precisely the β -quasi-elliptic symbols for β that consists of the rows of the matrix

 β -symbols

$$egin{aligned} \mathcal{A}(eta) = egin{pmatrix} 1_{k_1} & 0 & \cdots & 0 \ 0 & 1_{k_2} & \cdots & 0 \ dots & dots & dots & dots & dots \ dots & dots & dots & dots \ dots & dots & dots & dots \ 0 & 0 & \cdots & 1_{k_m} \end{pmatrix}, \end{aligned}$$

where $1_{k_j} = (0, \dots, 0, 1, \dots, 1, 0, \dots, 0)$ with entries 1 exactly at indices corresponding to k_j .

Similar constructions recover many other special symbols.

7 Spectral integral formulas

The use of moment map and their induced coordinates can be used to simplify the known spectral integral formulas for the MASGs.

Theorem (Q-Sanchez-Nungaray)

For every $\lambda > -1$ there exists a unitary map $R : \mathcal{A}^2_{\lambda}(\mathbb{B}^n) \to \ell^2(\mathbb{N}^n)$ such that for every essentially bounded quasi-elliptic symbol $a : \mathbb{B}^n \to \mathbb{C}$ of the form $a(z) = f(-\mu^{\mathbb{T}^n}(z))$ we have $RT^{(\lambda)}_a R^* = \gamma_{a,\lambda} I$, a multiplication operator, where $\gamma_{a,\lambda}$ is given by

$$\gamma_{\boldsymbol{a},\lambda}(\boldsymbol{p}) = \frac{\Gamma(\lambda+|\boldsymbol{p}|+n+1)}{\boldsymbol{p}!\Gamma(\lambda+1)} \int_{\mathbb{R}^n_+} \frac{f(\boldsymbol{u})\boldsymbol{u}^{\boldsymbol{p}}}{(1+|\boldsymbol{u}|)^{\lambda+|\boldsymbol{p}|+n+1}} \, \mathsf{d}\boldsymbol{u},$$

for every $p \in \mathbb{N}^n$.

Corollary (Q-Sanchez-Nungaray)

Let $\beta = \{v_1, \ldots, v_m\} \subset \mathbb{R}^n$ be a linearly independent set. Then, for every $\lambda > -1$ there exists a unitary map $R : \mathcal{A}^2_{\lambda}(\mathbb{B}^n) \to \ell^2(\mathbb{N}^n)$ such that for every essentially bounded β -quasi-elliptic symbol $a : \mathbb{B}^n \to \mathbb{C}$ of the form $a(z) = f(-A(\beta)\mu^{\mathbb{T}^n}(z)^{\top})$ we have $RT_a^{(\lambda)}R^* = \gamma_{a,\lambda}I$, a multiplication operator, where $\gamma_{a,\lambda}$ is given by

$$\gamma_{\boldsymbol{a},\lambda}(\boldsymbol{p}) = \frac{\boldsymbol{\Gamma}(\lambda + |\boldsymbol{p}| + n + 1)}{\boldsymbol{p}!\boldsymbol{\Gamma}(\lambda + 1)} \int_{\mathbb{R}^n_+} \frac{f(\boldsymbol{A}(\beta)\boldsymbol{u}^\top)\boldsymbol{u}^{\boldsymbol{p}}}{(1 + |\boldsymbol{u}|)^{\lambda + |\boldsymbol{p}| + n + 1}} \, \mathsf{d}\boldsymbol{u},$$

for every $p \in \mathbb{N}^n$. Here $A(\beta)$ denotes the matrix whose rows are the elements of β .

Toeplitz MASG Kähler manifolds Symplectic geometry Moment maps β-symbols Spectral formulas 000 0000 000000 000000 000000 000000

Theorem (Q-Sanchez-Nungaray)

For every weight $\lambda > -1$ there exists a unitary transformation $R : \mathcal{A}^2_{\lambda}(D_n) \to L^2(\mathbb{R}^{n-1} \times \mathbb{R}_+)$ such that for every essentially bounded nilpotent symbol $a : D_n \to \mathbb{C}$ of the form $a(z) = f(-\mu^{\mathbb{R}^n}(z))$ we have $RT^{(\lambda)}_a R^* = \gamma_{a,\lambda} I$, a multiplication operator, where $\gamma_{a,\lambda}$ is given by

$$\gamma_{a,\lambda}(y',\xi) = \frac{\xi^{\lambda+\frac{n+1}{2}}}{2^{n-1}\pi^{\frac{n-1}{2}}\Gamma(\lambda+1)} \int_{\mathbb{R}^{n-1}\times\mathbb{R}_+} \frac{f(u)e^{-\frac{\xi}{u_n}-\left|-\frac{\sqrt{\xi}u'}{2u_n}+y'\right|^2} du' du_n}{u_n^{\lambda+n+1}},$$

for every $y' \in \mathbb{R}^{n-1}$ and $\xi \in \mathbb{R}_+$.

For general β -nilpotent symbols it is enough to replace f(u) with $f(A(\beta)u^{\top})$.
